This is the **UCI Adult Census** dataset with **48,842 rows** and **14 features**. The target `income_label` is binary with mild class imbalance (76/24). Key signals include **age-income correlation** ($r=0.34$) and **high right-skew** in `capital_gain`. Well-suited for binary classification — only 0.3% missing values.

Recommendations

Ranked ML architectures for your binary classification task

#1

Gradient Boosting (XGBoost)

Ensemble · Decision Trees · Boosting

Excellent for tabular binary classification with mixed types. Handles the skewed capital_gain naturally via tree splits. Robust to mild class imbalance with scale_pos_weight tuning.

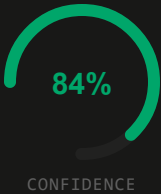

#2

Random Forest

Ensemble · Decision Trees · Bagging

Strong baseline with built-in feature importance. Less sensitive to hyperparameters than boosting. Good interpretability for the stakeholder-facing use case.

#3

Logistic Regression

Linear · Regularized · Fast

Interpretable baseline — fast to train and easy to explain. Establishes a performance floor for comparison.
